TITLE OF INVENTION

PROCESS FOR MELTING AND REFINING VITRIFIABLE MATERIALS

APPLICANT(S) FOR DO/EO/US

Pierre JEANVOINE, et al.

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1. ☒ This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2. ☐ This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371.
3. ☒ This is an express request to begin national examination procedures (35 U.S.C. 371(f)) at any time rather than delay examination until the expiration of the applicable time limit set in 35 U.S.C. 371(b) and PCT Articles 22 and 39(1).
4. ☐ A proper Demand for International Preliminary Examination was made by the 19th month from the earliest claimed priority date.
5. ☒ A copy of the International Application as filed (35 U.S.C. 371 (c) (2))
  - a. ☐ is transmitted herewith (required only if not transmitted by the International Bureau).
  - b. ☒ has been transmitted by the International Bureau.
  - c. ☐ is not required, as the application was filed in the United States Receiving Office (RO/US).
6. ☒ A translation of the International Application into English (35 U.S.C. 371(c)(2)).
7. ☒ A copy of the International Search Report (PCT/ISA/210).
8. ☒ Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371 (c)(3))
  - a. ☐ are transmitted herewith (required only if not transmitted by the International Bureau).
  - b. ☐ have been transmitted by the International Bureau.
  - c. ☐ have not been made; however, the time limit for making such amendments has NOT expired.
  - d. ☒ have not been made and will not be made.
9. ☐ A translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
10. ☐ An oath or declaration of the inventor(s) (35 U.S.C. 371 (c)(4)).
11. ☐ A copy of the International Preliminary Examination Report (PCT/IPEA/409).
12. ☐ A translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371 (c)(5)).

## Items 13 to 18 below concern document(s) or information included:

13. ☐ An Information Disclosure Statement under 37 CFR 1.97 and 1.98.
14. ☐ An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
15. ☒ A **FIRST** preliminary amendment.  
A **SECOND** or **SUBSEQUENT** preliminary amendment.
16. ☐ A substitute specification.
17. ☐ A change of power of attorney and/or address letter.
18. ☐ Certificate of Mailing by Express Mail
19. ☒ Other items or information:

Request for Consideration of Documents Cited in International Search Report

Claim 37, lines 1-3, replace "one of Claims 1 to 18 or the apparatus according to one of Claims 19 to 36" with --Claim 1--.

## REMARKS

Claims 1-37 are active in this application.

The claims have been amended to remove multiple dependencies. No new matter is believed to have been added to this application by these amendments.

Applicants submit that the present application is ready for examination on the merits. Early notice to this effect is earnestly solicited.

Respectfully submitted,

OBLON, SPIVAK, McCLELLAND,

PROCESS FOR MELTING AND REFINING

VITRIFIABLE MATERIALS

5 The invention relates to a process for melting  
and refining vitrifiable materials for the purpose of  
continuously feeding glass-forming plants with molten  
glass.

10 More particularly intended are plants for  
forming flat glass such as float or rolling plants, but  
also plants for forming glassware of the bottle or  
flask type, plants for forming glass fibres of the  
mineral wool type for thermal or acoustic insulation or  
else textile glass fibres called reinforcing fibres.

15 A great deal of research has been carried out  
on these processes, which schematically comprise a  
first melting step followed by a refining step intended  
to condition the molten glass thermally and chemically  
and in eliminating therefrom any batch stone, bubbles  
or any cause of defects appearing after forming.

20 In the melting range, it has thus been sought,  
for example, to speed up the melting process or to  
improve its energy efficiency. Mention may thus be made  
of the process consisting in rapidly heating the  
vitrifiable materials in a homogeneous and controlled  
25 manner while carrying out intense mechanical stirring  
allowing the still-solid vitrifiable materials to be  
brought into intimate contact with the already-liquid  
phase. This process is especially detailed in Patents  
FR-2,423,452, FR-2,281,902, FR-2,340,911 and  
30 FR-2,551,746 and generally uses electrical heating  
means of the submerged-electrode type.

35 Another type of melting process has been  
developed, for example of the type of those described  
in Patents US-3,627,504, US-3,260,587 or US-4,539,034  
which consist in using, as heating means, submerged  
burners, that is to say burners fed with gas and air,  
these generally being placed so as to be flush with the

09381631 030400

siege so that the flame develops within the mass of vitrifiable materials during liquefaction.

In either case, although it is possible actually to very significantly reduce the residence  
5 time of the vitrifiable materials in the melting chamber and to considerably increase the production efficiency compared with "conventional" melting operations, the molten glass being molten is, on the other hand, in the form of a foam which is difficult to  
10 refine - it is especially difficult to guarantee the quality of the final glass, especially optical glass.

Research has also been conducted in the refining field. Thus, a centrifugal refining process is, for example, known from Patent FR-2,132,028, this  
15 process using a device whose internal walls define a cylindrical chamber which has a vertical axis and is rotated. The molten glass feeds the device at the top and is distributed in the chamber, by defining a parabaloidal cavity which is established naturally due  
20 to the effect of the centrifugal force.

The object of the invention is therefore to improve melting and refining processes, aiming especially to use plants which are more compact and/or to have greater operating flexibility and/or greater  
25 production efficiency and/or to manufacture glass that has hitherto been difficult to melt or to refine and/or with a low energy cost, etc., without these industrial advantages being obtained to the detriment of the quality of the glass produced.

30 The subject of the invention is firstly a process for melting and refining vitrifiable materials, which is characterized by the combination of two characteristics:

→ on the one hand, all or part of the thermal energy  
35 necessary for melting the vitrifiable materials is supplied by the combustion of fossil fuel(s) with at least one oxidizer gas, the said fuels/gas or the

00331531 030100

gaseous products resulting from the combustion being injected below the level of the mass of vitrifiable materials,

→ on the other hand, the refining of the vitrifiable materials after melting takes place at least partly in the form of a "thin layer".

In the context of the invention, "thin-layer" refining should be understood to mean refining in which the molten vitrifiable materials are forced to flow over a very small depth/thickness - to be more specific, at most 15 cm and even at most 10 cm for example - this being achieved by various means. The molten materials may especially be forced to flow between two physical walls close together, the distance separating them defining the depth/thickness of the thin layer (the flow being obtained by the centrifugal force or simply by gravity, for example). These thin-layer characteristics may also be obtained by other means, especially by the choice of the dimensions of the refining compartment or compartments, the choice of the means for feeding them as input or for drawing them off as output. Some of these means will be explained below. In fact, the major advantage of thus imposing a small thickness on the stream of vitrifiable materials being refined is that it is thus possible to considerably reduce the path taken by bubbles contained in these molten materials to the free surface of the latter or to the walls that they are forced to hug, and that this makes it easier for these bubbles to burst and be removed.

There has in fact proved to be an extremely advantageous synergy from an industrial standpoint between the use of melting called hereafter "melting by submerged burners" for the sake of simplicity and that of "thin-layer" refining as defined previously.

However, since this combination is far from being imposed as evidence, it might be expected that

09381631.030100

all the advantages mentioned above would be obtained only at the price of mediocre glass quality, which has not been the case. This is because, in the invention, very particular refining is used by additionally  
5 changing a size parameter, namely instead of feeding the refining zone with "conventional" molten glass to be refined, it is fed here in fact with a glass obtained by melting by submerged burners, that is to say with glass having very special characteristics in  
10 the sense that it is foamy throughout, with a relatively low density compared with that of a standard glass to be refined. Nothing would suggest that an initially relatively foamy glass could be refined in a thin layer.

15 Surprisingly, this has proved to be possible as it has been discovered that this foamy glass resulting from melting by submerged burners also had the characteristic of containing relatively large bubbles; if it is actually in the form of a kind of foam which  
20 remains to be refined, it is possible to control the size of the bubbles which it contains and, especially in certain preferred configurations and for certain compositions of vitrifiable materials, to remove almost all the smaller bubbles, that is to say those having a  
25 diameter of approximately less than 100  $\mu\text{m}$  and even less than 200  $\mu\text{m}$ , by carrying out, on this glass while it is being melted, a kind of "microrefining" prior to the actual refining after the melting, this  
30 microrefining facilitating the coalescence of the bubbles and the disappearance of the smaller bubbles in favour of the larger ones and being promoted by the addition into the vitrifiable materials of refining promoters of the coke or sulphate type. Furthermore, this glass leaving the melting chamber generally has a  
35 relatively low residual amount of batch stone: the combination of "large" bubbles and little batch stone thus allows the use of thin-layer refining, greatly

facilitating the refining, at least part of which is to have already been carried out *de facto* during the melting. "Large" bubbles have a greater speed of ascent, coalesce more quickly and finally are removed  
5 more quickly.

It should also be noted that, in general, the glass melted by submerged burners only contains a little sulphate, the residual amount of which before refining is less than 600 ppm, especially less than 200  
10 or 100 ppm, or even less than 50 ppm expressed by weight of  $\text{SO}_3$ , whatever the type of vitrifiable material, which may or may not contain unintentional sulphates or which even may have sulphates added to them. This would be explained by the partial pressure  
15 of water generated by the submerged combustion.

It should be noted that a desulphated glass gives fewer problems of volatile compounds in the float bath, fewer risks of the formation of tin sulphide and therefore, finally, fewer risks of a tin defect in the  
20 sheet of glass. This decreases the amount of sulphides (or even eliminates them completely) in the case of reduced glasses, especially iron sulphides which give undesirable yellow/amber residual colours or nickel sulphide inclusions which may cause the glass to break  
25 during quenching-type heat treatments.

The invention therefore makes it possible optionally to have glasses which are very low in sulphate even before the refining operation, therefore glasses which are at least as low after refining, this  
30 being so without having to purify/select vitrifiable materials so that they are low in sulphate. On the contrary, it is even possible to add sulphate at the start.

One advantageous effect obtained by the  
35 combination according to the invention relates to the energy cost of the process: melting by submerged burners makes it possible to avoid using electrical

melting of the submerged-electrode type, the cost of which may be very significant depending on the country. Furthermore, and this is the most important point, melting by submerged burners creates convective stirring within the vitrifiable materials during liquefaction, as explained in detail below. This very strong mixing between materials not yet liquefied and those which are already molten is extremely effective and makes it possible to achieve, for vitrifiable materials of the same chemical composition, melting at a lower temperature and/or melting which is much more rapid than with conventional heating means.

The temperatures encountered in melting may be everywhere lower than in the usual processes, something which is economically very advantageous, simply in terms of energy cost, but also by the selection of refractory-type materials used in the manufacture of the plants - materials which are less hot corrode more slowly.

The residence times in the melting and refining zones are significantly reduced and are compatible, this obviously having a very positive effect on the production efficiency and on the output of the plant in its entirety. At the same time, the invention makes it possible to obtain plants which are very compact - this is because melting by submerged burners, again due to the very strong mixing that it causes, allows the size of the melting chamber to be considerably reduced. Furthermore, thin-layer refining has the same consequences on the size of the compartment(s) where this operation is carried out. Thus, by reducing the glass depth during the refining, the bubbles are removed more quickly and it is therefore possible to considerably reduce the "length" (in the direction of flow of the glass) of the refining compartment or compartments. Overall, the plant may therefore be very compact, with clear advantages in terms of construction

leading moreover to a completely "clean" process, that is to say without the emission of nitrogen oxides,  $\text{NO}_x$ , or of greenhouse gases of the  $\text{CO}_x$  type, other than that which may arise from the decarbonization of the batch materials.

Advantageously, the melting is carried out according to the invention in at least one melting chamber which is equipped with burners which are placed so that their combustion regions or combustion gases develop in the mass of vitrifiable materials during melting. They are thus made to pass through its side walls and/or the siege and/or they are suspended from the top, fastening them to the roof or to any suitable superstructure. These burners may be such that their gas supply pipes are flush with the wall through which they pass. It may be preferable for these pipes to "enter", at least partly, the mass of vitrifiable materials so as to prevent the flames from being too great near the walls and not to cause premature wear of the refractory materials. It is also possible to choose to inject only the combustion gases, the combustion regions being produced outside the melting chamber proper.

As mentioned above, it has turned out that this method of heating caused intense convective stirring of the vitrifiable materials - convection loops thus form on each side of the combustion regions or "flames" or streams of combustion gases, permanently mixing the molten and not yet molten materials very effectively. This thus results in the highly favourable characteristics of "stirred" melting, without having to make use of mechanical stirring means which are not very reliable and/or subject to rapid wear.

Preferably, the height of the mass of vitrifiable materials in the melting chamber and the height at which the combustion regions or gases resulting from the combustion develop are adjusted so

5 In general, this type of melting makes it possible to considerably reduce the emission of any type of dust in the melting chamber and of any gas of the NO<sub>x</sub> type since heat exchange takes place very quickly, thereby avoiding the temperature peaks likely  
10 to be conducive to the formation of these gases. It also considerably reduces the emission of gases of the CO<sub>x</sub> type, the total energy consumption of the plant being lower than with conventional apparatuses using fired furnaces, for example those operating in down-  
15 draught mode.

25       The vitrifiable materials may comprise batch materials, but also cullet or even scrap intended to be vitrified. They may also comprise combustible elements (organic matter): it is thus possible to recycle, for example, mineral fibres which have been sized with  
30 binder (of the type used in thermal or acoustic insulation or of those used in the reinforcement of plastics), window panes laminated with sheets of polymer of the polyvinyl butyral type, such as windscreens, or any type of "composite" material which  
35 combines glass with plastics, such as certain bottles. It is thus possible to recycle "glass/metal or metal compound composites" such as window panes

functionalized with coatings containing metals, these being difficult hitherto to recycle since this would run the risk of gradually enriching the melting chamber with metals which would build up on the surface of the  
5 siege. However, the stirring caused by the melting according to the invention prevents this sedimentation and thus allows, for example, window panes coated with layers of enamel, with layers of metal and/or of various connection elements to be recycled.

10 The subject of the invention is also the recycling of all these composite elements containing glass because of the melting by submerged burners in a glass furnace. In particular, furnaces with submerged burners may be provided, the essential function of  
15 which is the manufacture of a cullet from these various materials to be recycled, which particular cullet may then serve, possibly combined with standard cullet, as batch materials for conventional glass furnaces.

Advantageously, provision may be made to  
20 introduce all or part of the vitrifiable materials into the melting chamber below the level of the mass of vitrifiable materials being melted. Some of these materials may be conventionally introduced from above the mass being liquefied and the rest from below, for  
25 example by supply means of the feed-screw type. The materials may thus be introduced directly into the mass being liquefied, at a single point or at various points distributed over the walls of the melting chamber. Such an introduction directly into the mass of materials  
30 being liquefied (hereafter referred to as the "melt") is advantageous for more than one reason: firstly, it considerably reduces any risk of batch materials flying off above the melt, and therefore reduces the amount of solid dust emitted by the furnace to the minimum. Thus,  
35 it allows better control of the minimum residence time of the said materials before they are extracted into the refining zone and allows them to be selectively

introduced at the point where the convective stirring is the strongest, depending on the arrangement of the submerged burners. This or these points of introduction into the melt may thus be near the surface or more  
5 deeply in the melt, for example at a melt height of between 1/5th and 4/5ths of the total height of the melt above the level of the sieve, or else between 1/3 and 2/3 of the said height.

It has been seen that the process according to  
10 the invention made it possible to recycle plastics in the form of composite products combined most particularly with glass, these plastics thus serving as part of the fuel. It is also possible, and advantageous, to introduce all or part of the fuel  
15 necessary for the melting by submerged burners in the form of a solid fuel (polymer-type organic materials or coal) or even a liquid fuel, this fuel being a partial substitute for at least the liquid (especially fossil) or gaseous fuels feeding the burners. In general, the  
20 term "vitrifiable materials" or "batch materials" used in the present text is intended to encompass the materials necessary for obtaining a glassy (or ceramic or glass-ceramic) matrix, but also all the additives (refining additives, etc.), all the optional liquid or  
25 solid fuels (plastic of composite or non-composite material, organic matter, coal, etc.), and any type of cullet.

It is also possible to recycle window panes laminated with sheets of polymer of the polyvinyl  
30 butyral type, such as windscreens with which vehicles are equipped, or other types of composite materials which combine glass with plastics, such as certain bottles for example.

It is also possible to recycle window panes  
35 functionalized with coatings containing metals, these being difficult hitherto to recycle since this would run the risk of gradually enriching the melting chamber

with metals that would build up on the surface of the  
siege. However, the stirring caused by the melting  
according to the invention prevents this sedimentation  
and thus allows, for example, window panes coated with  
5 layers of enamel, with layers of metal or of various  
connection elements to be recycled.

The process according to the invention may  
operate with a high level of cullet.

As mentioned above, the refining according to  
10 the invention is therefore carried out on molten  
vitrifiable materials of the glass type in the  
relatively foamy state. Typically, this "foam" has a  
density of approximately 0.5 to 2 g/cm<sup>3</sup>, especially 1 to  
2 for example (to be compared with a density of about  
15 2.3 or 2.4 in the case of non-foamy glass), it may have  
a sulphate content of at most 600 or even of at most  
100 ppm expressed by weight of SO<sub>3</sub> and above all it may  
contain most of the bubbles having a diameter of at  
least 100 or 200 μm.

20 In order to improve the performance  
characteristics of the refining operation, various  
refining promoters are preferably added to the  
vitrifiable materials, the aim being especially to  
remove from the glass any bubbles having a diameter of  
25 less than 100 and even less than 200 μm right from the  
melting stage, as mentioned above. These may be  
reducing additives, such as coke (which also allows the  
redox of the glass to be adjusted). In this case, it is  
advantageous to select coke powder which has an average  
30 particle size of less than 200 μm. They may also be  
sulphates. Other refining promoters will be effective  
rather more during the stage of the refining proper,  
after the melting stage. They allow the foam to be  
"destabilized": they may, for example, be fluorine or a  
35 fluorine or chlorine compound, more generally halides,  
or else a nitrate of the NaNO<sub>3</sub> type; fluorine (halogen)  
seems to lower the viscosity of the glass and thus

helps to drain the films which form between the bubbles, which draining promotes collapse of the foam. It also lowers the surface tension of the glass.

Advantageously, the process according to the invention makes it possible to carry out the melting at temperatures not exceeding 1400°C, especially at 1380 or 1350°C, and the refining at temperatures not exceeding 1500°C.

According to a first variant, the refining according to the invention may be carried out in at least one static compartment (one which does not move during operation) downstream of the melting chamber, of the flow-canal type, and provided with one or more means for forcing the molten vitrifiable materials to be refined in a thin layer, especially to a depth of at most 15 cm or of at most 10 cm. These one or more means may also advantageously help to avoid the formation of a return glass current in the mass of molten vitrifiable materials flowing in the said compartment(s). The "return current" refers to convective recirculation loops that are found within the vitrifiable materials in most conventional refining compartments. For more details regarding one non-limiting way of eliminating this return current and regarding the advantages which are connected therewith, reference may advantageously be made, for example, to Patent EP-616,983.

It has in fact turned out that a very great advantage associated with a thin-layer flow was that any return current could be eliminated, while having a flow in the refining compartment of the plug-flow type. In plug flow, the molten materials no longer have a downward-directed velocity component and the bubbles, tending to rise to the surface of the glass, can no longer be forced to "dive down" again into the bath by entrainment due to the convective recirculation currents, which are thus eliminated.

According to a second variant, the thin-layer refining is carried out either in the melting chamber itself or in at least one static compartment located downstream thereof, by giving the molten vitrifiable materials, by gravity, a downward path between at least two adjacent walls, these being essentially mutually parallel, at least partially submerged in the molten mass and inclined with respect to the plane of the sieve of the melting chamber or compartment (or, in other words, walls which are inclined in essentially mutually parallel planes inclined with respect to the longitudinal axis of the melting chamber or of the downstream compartment in question). Advantageously, these walls may be incorporated into one or more structural elements such as tubular elements, especially having an approximately rectangular cross section, which are longitudinally partitioned (by a plurality of partitions): refining is thus obtained by forming a plurality of thin layers of glass to be refined which flow along "lamellae" consisting of the abovementioned walls, the method of operation of this refining being explained in detail below with the aid of the figures.

According to a third variant, the refining is carried out downstream of the melting chamber, but in a compartment capable of being rotated so as to ensure centrifugal refining, this compartment furthermore being provided with one or more means of forcing the molten vitrifiable materials to be refined in a thin layer to a "relative thickness"  $R1/R0$  of at least 0.8 or, in absolute values, to an "absolute thickness" of at most 10 cm.

Within the context of the invention, the ratio  $R1/R0$  should be understood in the following manner:  $R0$  is the average radius of the approximately cylindrical cavity defined by the compartment, through which cavity the molten material flows, and  $R1$  is the average radius

of the partitioning means introduced into the cavity in order to force the molten materials to follow a path between the internal walls of the cavity and the partitioning means.

5           A third variant consists in combining the two previous ones, especially by using, for the refining, a static first compartment and then a rotating second compartment.

          (In the context of the invention, the terms  
10 "upstream" and "downstream" refer to the direction of flow of the glass through the plant from the point where the vitrifiable materials are fed into the melting chamber to the point where the refined glass is extracted).

15           The melting/refining process according to the invention allows glasses of highly varied compositions and properties to be manufactured. Moreover, it makes it possible, because of its low inertia, to switch from one composition to another with very short transition  
20 times. It allows refined molten glass to be fed into plants for forming flat glass, hollow-ware, glass wool, or glass fibre for reinforcement.

          It thus allows relatively reduced glasses, especially those having a redox of greater than or  
25 equal to 0.3, to be manufactured. (The redox is defined as the ratio of the ferrous iron FeO content, as a percentage by weight, to the total iron content by weight of the composition expressed in the form of Fe<sub>2</sub>O<sub>3</sub>).

30           It also allows glasses having a high SiO<sub>2</sub> content, for example at least 72 or even at least 75% by weight, to be manufactured, these glasses generally being difficult to melt but advantageous, especially in terms of batch material cost, because they have a low  
35 density and are very compatible with plastics. It also makes it possible to manufacture quite special glasses, having a high alkaline-earth oxide content, for example

containing at least 18% by weight of CaO, which glasses are, however, quite corrosive using the conventional melting processes at a higher temperature than in the invention, as well as glasses having a low sodium oxide  
5 content of at most 11% by weight for example, or having a very low sulphate content, for example of at most 600 ppm. Glasses containing iron, with a high redox but a low sulphate content also allow glasses to be obtained which have a residual blue colour which is  
10 particularly attractive and sought after in the field of flat glass for motor vehicles and for buildings, for example. Highly selective solar-protection glasses may thus be obtained on which may be deposited solar-protection layers in order to enhance the thermal  
15 performance characteristics thereof, for example layers of the TiN type, these being described especially in Patents EP-638,527 and EP-511,901.

The subject of the invention is also a melting and refining apparatus which is especially suitable for  
20 implementing the process described above and which comprises:

→ at least one melting chamber equipped with burners which are fed with fossil fuel(s) of the (natural) gas type and with oxidizer(s) of the air or oxygen type,  
25 the said burners being placed so as to inject these gases or the gases resulting from the combustion below the level of the mass of vitrifiable materials introduced into the said melting chamber,

→ means for forcing the molten vitrifiable materials  
30 to be refined in the form of a "thin layer", the said means being included in the melting chamber itself or in at least one refining compartment downstream of this chamber.

Advantageously, as mentioned previously, the  
35 melting chamber may be equipped with at least one means of introducing vitrifiable materials below the level of the melt, especially at least two of them, preferably

in the form of an opening (or openings) in the associated wall(s), with a supply means of the feed-screw type. The risks of dust flying off are thus minimized, while at the same time also optionally  
5 allowing the introduction, above the melt, of the vitrifiable materials, such as silica, on which a preheating operation may be carried out without the risk of them setting solid.

Independently of the refining operation too,  
10 the invention also depends on design improvements with regard to the walls of the melting chamber which are intended to be in contact with the melt. Several variants are possible. In certain cases, known oxide-based refractory materials may be simply used, such as  
15 alumina, zirconia, chromium oxide and so-called AZS (alumina-zirconia-silica) refractories. It is generally preferred to combine them with a cooling system involving the circulation of a fluid of the water type (water jacket). The water jacket may be placed on the  
20 outside, the refractories then being in direct contact with the glass, or on the inside. The water jacket then has the function of creating a cooler stream of glass near the refractories, these being particularly stressed in this context as the melt generated by the  
25 submerged burners causes strong convective currents against the walls.

Another variant consists in using, in the melt zone, not refractories but only the abovementioned water jacket.

30 Another variant consists in using refractory materials (optionally combined with a cooling system of the water-jacket type) and in lining them with a lining made of a highly refractory metal such as molybdenum (or an Mo alloy). This lining may advantageously be  
35 held at some distance (for example from 1 to a few millimetres) from the walls of the refractories and may present the melt with a continuous contact surface

(solid plate or plates made of Mo) or a discontinuous contact surface (Mo plate or plates drilled with holes). This lining has the purpose of mechanically preventing direct convection of the glass onto the refractories by generating a "still" layer of glass along the refractories, or even by preventing any contact of the glass with the latter.

In the melting chamber, all or some of the submerged burners are preferably designed so that they can inject, into the melt, a fluid which does not participate in the combustion by substituting (temporarily) for the oxidizer and/or the fuel. This fluid may be an inert gas of the  $N_2$  type or a coolant of the liquid-water type which immediately vaporizes in the melt. The fact of thus temporarily stopping the combustion, while continuing to inject a fluid at the burner, generally has two objectives: either it is desired to stop the operation of the burner and more generally, for example, of the melting chamber in its entirety, the injection of inert gas of the  $N_2$  type allowing the chamber to be made safe in the region of the burners, or it is desired to change the burner for another while the other burners are operating and while it is therefore still in the presence of a glass melt. In this case, as explained in detail below, spraying water suitably via the burner allows the glass above the burner to be temporarily frozen, creating a kind of "bell", which allows a time long enough to carry out the change without glazing the burner.

According to the first variant mentioned above, the refining compartment is static. It includes a flow canal comprising a channel and a roof. The means for forcing the molten vitrifiable materials to be refined in the canal as a thin layer, especially to a depth of less than 15 cm, thus creating a plug-type flow, are, for example, of the structural kind and comprise appropriately selecting the ratio of the average height

[illegible]

100

being rotated in order to ensure centrifugal refining, the internal walls of the said device substantially defining the shape of a hollow vertical cylinder, at least in its central part.

5           In order to force the vitrifiable materials to flow as a thin layer through this centrifugal device, the cavity in the latter may advantageously be equipped with one or more partitions, at least over part of its height, forcing the molten materials to flow between  
10 the internal walls of the device and these partitions, the average distance between the walls and the partitions defining the "thickness" of the thin layer. In fact, according to the invention, the parabolic profile adopted naturally by the molten glass when it  
15 is "freely" centrifuged, i.e. only contained by cylindrical-type external walls, is prevented from forming. In contrast, according to the invention, the glass is obliged to hug the walls of the device and the partitions installed in the body of the centrifuger, to  
20 a relatively constant thickness over the height of the centrifuger, and to a much smaller depth than if the abovementioned paraboloidal profile had been left to form. There is thus a considerable gain in efficiency, the bubbles bursting under the centripetal force much  
25 more quickly on the partitions, the path of the bubbles being much shorter. As in the static variant, the flow may be referred to as plug flow. This allows the height of the centrifuger to be reduced, with its size retaining the same performance characteristics.  
30 Preferably, the distance between partitions and walls is at most a few centimetres or is defined by the  $R1/R0$  ratio of at least 0.8, the ratio being explained above.

          According to a preferred design, the device is fed at the upper part with molten vitrifiable materials  
35 by a static supply means of the flow-canal type. These supply means may comprise at least one compartment at reduced pressure in order to allow the device to be fed

00381631 030100

and/or to allow a first refining operation to be carried out.

The device may advantageously be provided with means for trapping solid particles having a density greater than that of the glass, these means especially being located in its lower zone and being in the form of notches/grooves made in its internal walls. Preferably, the speed of rotation of the device is selected to be between 100 and 1500 revolutions per minute.

The device may also be provided with mechanical means which are stationary or which follow its rotation, and are capable of shearing the foam and of driving it downwards into the lower zone of the device from which the refined glass is drawn off. These means are especially in the form of pierced deflectors, or fins placed in the upper zone of the said device.

The invention will be explained in detail below with the aid of three non-limiting embodiments illustrated by the following figures:

□ **Figure 1:** a diagrammatic melting/refining plant using a static refining apparatus;

□ **Figure 2:** a diagrammatic melting/refining plant using a centrifugal refining apparatus;

□ **Figure 3:** an enlarged view of the refining apparatus of the plant according to Figure 2;

□ **Figure 4:** a schematic melting/refining plant using refining by lamellae in the actual melting chamber; and

□ **Figure 5:** a schematic cross-sectional view of a submerged burner fitted into the melting chamber of the plants shown in the preceding figures.

These figures are not necessarily to scale and for the sake of clarity have been extremely simplified.

The apparatuses described below are designed to melt and refine glasses of highly varied compositions,

09381631.030100

in this case glasses intended to feed a float plant for producing flat glass. But this application is not limiting. These glasses may also feed, for instance, equipment for forming glass hollow-ware or fiberizing equipment of the internal-centrifuging device type.

Furthermore, of course, all the standard glasses of the silica-soda-lime type and various type of special glasses are particularly advantageous to manufacture using the apparatuses according to the invention, especially those deemed hitherto to be difficult to melt:

→ glasses having a low  $\text{Na}_2\text{O}$  content and a relatively high alkaline-earth oxide, especially  $\text{CaO}$ , content, this being advantageous from an economic standpoint in terms of the cost of batch materials, but also glasses which are quite corrosive at conventional melting temperatures and which are relatively hard to melt using standard processes. These may be the glass compositions described, for example, in Patent FR 97/08261 of 1 July 1997, such as (in % by weight):

	$\text{SiO}_2$	72 - 74.3%
	$\text{Al}_2\text{O}_3$	0 - 1.6%
	$\text{Na}_2\text{O}$	11.1 - 13.3%
	$\text{K}_2\text{O}$	0 - 1.5%
25	$\text{CaO}$	7.5 - 10%
	$\text{MgO}$	3.5 - 4.5%
	$\text{Fe}_2\text{O}_3$	0.1 - 1%

or else of compositions of the type (expressed in percentages by weight):

30	$\text{SiO}_2$	66 - 72, especially 68 - 70%
	$\text{Al}_2\text{O}_3$	0 - 2%
	$\text{Fe}_2\text{O}_3$	0 - 1%
	$\text{CaO}$	15 - 22%
	$\text{MgO}$	0 - 6, especially 3 - 6%
35	$\text{Na}_2\text{O}$	4 - 9, especially 5 - 6%
	$\text{K}_2\text{O}$	0 - 2, especially 0 - 1%

09381631 030100

SO<sub>3</sub> traces.

Another example illustrating this family of compositions is as follows:

	SiO <sub>2</sub>	69%
5	Al <sub>2</sub> O <sub>3</sub>	1%
	Fe <sub>2</sub> O <sub>3</sub>	0.1%
	CaO	18.9%
	MgO	5%
	Na <sub>2</sub> O	5.6%
10	K <sub>2</sub> O	0.3%
	SO <sub>3</sub>	traces.

This glass has a lower annealing temperature, also called the strain-point temperature, of 590°C (at which temperature the glass has a viscosity of 1014.5 poise). It also has a liquidus temperature of 1225°C, a temperature  $T_{\eta = \log 2}$  of 1431°C and a temperature  $T_{\eta = \log 3.5}$  of 1140°C ( $T_{\eta = \log 2}$  and  $T_{\eta = \log 3.5}$  correspond to the temperatures that the glass has when it reaches a viscosity, in poise, of log2 and log3.5, respectively). It has fire-resistant glass properties resulting from its high softening point (greater than 800°C) and properties suitable for it to be applied in plasma screens because of its high "strain point".

→ glasses having a high silica content, these also being advantageous from the economic standpoint, and having a relatively low density, the compositional ranges of which, again expressed in percentages by weight, are as follows:

	SiO <sub>2</sub>	72 to 80%
30	CaO + MgO + BaO	0.3 to 14%
	Na <sub>2</sub> O	11 to 17%
	alkaline oxides	11 to 18.5%
	Al <sub>2</sub> O <sub>3</sub>	0.2 to 2%
	B <sub>2</sub> O <sub>3</sub>	0 to 2%
35	Fe <sub>2</sub> O <sub>3</sub>	0 to 3%
	SO <sub>3</sub>	optionally traces

coke 0 - 600 ppm

and optionally colouring oxides, for example the oxides of Ni, Cr, Co, etc.

(These glasses have the feature of being particularly viscous).

An example illustrating this family of compositions is as follows:

	SiO <sub>2</sub>	76.4%
	Fe <sub>2</sub> O <sub>3</sub>	0.1%
10	Al <sub>2</sub> O <sub>3</sub>	0.1%
	CaO	7.6%
	MgO	5%
	Na <sub>2</sub> O	10%
	K <sub>2</sub> O	0.3%.

It has a relative density of approximately 2.46 (compared with relative densities of 2.52 for the standard silica-soda-lime glass of the "Planilux" type sold by Saint-Gobain Vitrage).

→ It was also seen above that the process according to the invention could be used to obtain reduced glasses, the high redox, the iron content and the very low sulphate content of which allow glasses with a residual blue colour to be obtained.

→ Using the process according to the invention, it is also possible to manufacture glasses having a zero or almost zero content of alkali metal oxides of the Na<sub>2</sub>O type, especially for the purpose of applications for fire-resistance glazing or for substrates used for the electronics industry. For such compositions, reference may be made especially to Patents EP-526,272 and EP-576,362.

Other glasses, especially those having a low MgO content, of the type described in Patents EP-688,741 and WO 96/00194 may also be manufactured using the process of the invention.

A first method of implementation is therefore shown in Figure 1: a canal 1 simultaneously allows some

00331531 030100

of the vitrifiable materials to be introduced into the melting chamber 2 via the roof 3 and the combustion smoke to be removed. This smoke will preheat the vitrifiable materials, its thermal energy thus being recovered.

The batch materials capable of thus being introduced above the melt 7 especially comprise silica, which can be preheated without setting into a solid mass. The rest of the batch materials are injected at at least one point 1' located below the level of the melt 7, especially via an opening fed via a feed screw. Only one injection point has been shown here, this being furthermore placed rather high up with respect to the total height B of the melt, at about  $2/3$  of this height and on the front wall of the chamber.

In fact, several injection points may be provided in the walls (front walls or side walls) which may or may not be at this same height, especially in the upper half or in the lower half of this height B, for example between  $1/3$  and  $2/3$  of this height. In fact, this injection directly into the melt makes it possible to greatly reduce the amount of material flying off above the melt (emission of solid dust particles). Furthermore, depending on its configuration, it makes it possible to direct the materials at the point where the convective stirring is strongest and/or to take account of this in order for these materials to remain for at least the minimum period of time in the chamber 2 before passing into the refining zone.

The siege 4 of the chamber is equipped with rows of burners 5 which pass through it and penetrate into the melting chamber over a small height. The burners 5 are preferably provided with cooling means, not shown, of the water-jacket type. The burners 5 in operation develop combustion regions in zones 6, creating, near them, convective streams within the

5 vitrifiable material being liquefied. This convective stirring creates a foam which will transfer the thermal energy throughout the melt 7. The melting preferably takes place at about 1350°C, for example in the case of a standard glass of the family of silica-soda-lime glasses.

10 The walls of the chamber 2 which are in contact with the melt 7 here are made of refractory materials cooled, on the outside, by a cooling system of the water-jacket type (not shown). A variant consists in that this cooling system, with metal walls, lies against the refractories but on the inside and is therefore in contact with the melt. These two variants make it possible to slow down the wear of the refractories by superficially cooling the glass near the walls of the refractories.

20 The operation of the burners 5 has been adapted to submerged melting in the manner shown very diagrammatically in Figure 5. Figure 5a shows a longitudinal section of a burner 5 and Figure 5b shows a cross section, in the plane AA' indicated in Figure 5a of the latter. The burner is jacketed with a cooling system 60 of the water-jacket type and has a central pipe 61 around which are concentrically placed a plurality of pipes 62, all these pipes of cylindrical section emerging in the nose of the burner 63.

30 In normal operation (operation [a]), the pipe 61 is fed with a combustible gas of the natural-gas type (or another combustible gas or fuel oil) and the pipes 62 are fed with oxidizer, in this case oxygen for example, the  $\text{CH}_4/\text{O}_2$  interaction creating a combustion region in the melt.

35 In safety operation (operation [b]), that is to say when it is desired to stop the combustion at the burner without the risk of it being completely glazed, nitrogen is injected via the pipe 61 and/or via the pipes 62.

In operation intended to allow the burner to be exchanged for another (operation [c]), water is injected via the pipe 61, which water instantly vaporizes in the burner even in or right after leaving the burner, the vapour creating a kind of roof of cooled glass above the burner; any operation of the burner is then stopped and there is then enough time to carry out the exchange before the "roof" collapses. The injected water is at least partially collected in the burner by the pipes 62 (the roles of the pipes 61 and 62 in this operating mode may also be reversed). Any other coolant being thus able to freeze the glass may also be substituted.

The burner and its various operating modes described above form one subject of the invention, independently of the overall melting and refining operation involved in the glass plant.

The molten foamy glass resulting from the melting by submerged burners is then drawn off at the bottom part by a canal 8 optionally provided with means for adjusting the plug-type flow (not shown). The flow of the foamy glass entering the static refining compartment can thus be controlled. This compartment is in the form of a channel 9 defined by a runner 10 and a roof 11. It is equipped with oxygen burners 12. The vitrifiable materials flow through the channel, without a return current, over a height H of approximately 5 to 10 cm. This height is adjusted so as to have the desired plug flow in the channel 9, taking into account the densities of the molten materials in the melting chamber 2 and in the channel 9, as well as the heights 11 and 12 of the melts in these two zones. In order to obtain the desired thin layer, it is necessary here to raise the level of the channel 10 of the channel 9 with respect to that of the siege 4 of the chamber 2.

On the output side of the channel 9, a submerged dam 13 emerged to an adjustable depth in the

09381631 030100

melt allows the output flow to be adjusted; the refined glass pours out at the end of the channel 9 in order to feed a forming plant, here the chamber of a float bath for example. The refining is therefore carried out over  
5 a very shallow depth of glass, which shortens the path of the bubbles to the surface (their rate of rise being further facilitated when they are already predominantly at least 200  $\mu\text{m}$ ) and, because of the plug flow obtained, prevents them from sinking again in the  
10 course of rising in the melt.

Figures 2 and 3 show a second embodiment.

The significant difference compared with Figure 1 resides in the way in which the walls of the refractories of the chamber 2 are protected. Here,  
15 submerged in the melt 7, there is a lining of refractory metal consisting of a thin wall 40 of molybdenum matching the shape of the cavity of the melting chamber and held in place at a distance of from one to a few millimetres from the walls of the  
20 refractories by means of suitable spacers and/or by being suspended in the melt from the walls of the refractories located above the melt or from the roof.

This sheet 40 is drilled with holes, firstly in its horizontal zone lining the siege 4, so as to be  
25 able to be penetrated by the burners 5, as well as in all its other walls, with a homogeneous distribution in the holes: this piercing therefore does not prevent contact between the refractories and the molten glass, however it mechanically breaks the convection movements  
30 of the glass near the refractories and thus reduces their rate of wear. The holes 41 in the walls of the lining 40, apart from those lining the siege, are preferably cylindrical and of varying dimensions, those in the wall on the siege side having at least to  
35 comprise holes 42 whose size is sufficient to allow the burners 5 to pass through them. The lining 40 must also be widely pierced (at 43) in its wall lining the

00384531 000100

5 the holes made in the walls made of refractories and in  
the lining made of molybdenum.

10 of the way in which any subsequent refining may be  
carried out. (The same applies to the cooling, on the  
external side or the glass side, of the refractories,  
illustrated in the previous figure.)

15 the way in which the glass is drawn off from the  
melting chamber. In the case of Figure 2, the glass is  
drawn off slightly "higher up", with a supply pipe 20  
split into a horizontal first part 20(a), a vertical  
second part 20(b) and a horizontal third part 20(c)  
20 feeding the apparatus of the centrifuger 21. Another  
variant consists in the molten glass being drawn off  
from the melting chamber at the top, for example by  
means of a submerged canal as is well known to those in  
the glass-making field.

25           Figure 3 concentrates on the horizontal zone  
20(c) of the canal 20 for supplying the molten foamy  
glass 20, drawn off from the melting chamber 2, which  
feeds the body of the centrifuger 21 via a pipe 20'.  
The centrifuger 21 has an upper part 22 lying between  
30 the neck 35 fed with glass to be refined and the metal  
plate 24, and a lower part 30 lying beneath the metal  
plate 24. Means (not shown) intended to control the  
flow of glass entering the centrifuger may be provided.

35 centrifuger is stopped in its fall by the metal plate  
24 which, in combination with the upper part of the  
partition 34 described above, creates a kind of

collector "basket". Due to the centrifugal force, the glass tends to rise in the zone 26 and then to pass over the partition 34; it thus flows from the zone 26 into the zone 30 in the form of a thin layer contained  
5 by the internal wall 33 of the centrifuger 21 on the one hand and by the partition 34 placed in the cavity of the centrifuger on the other hand. The internal wall 33 is approximately in the form of a cylinder of radius  $R_0$  and the partition 34 has a cylindrical zone 34(a) of  
10 radius  $R_1$ , this zone being closed in the bottom part in the zone 34(b). The partition 34 is provided with centring means (not shown), just like the plate 24. Shown diagrammatically in dotted lines is the parabolic shape that the glass would have due to the centrifugal  
15 effect if there were no partition 34.

The partition 34 and the plate 24, may be made of molybdenum, at the very least for the parts which are completely submerged in the glass.

The outer shell of the internal wall 33 of the  
20 body of the centrifuger 21 may consist of electrocast refractory pieces 32 comprising a thermal insulator 31 incorporated so that the latter is not crushed by the centrifugal force. Also provided is a notch or groove 28 which goes around the internal wall of the part 30  
25 (or is discontinuous), thereby allowing all the solid particles of density greater than that of the glass, of the refractory-inclusion type, to be trapped. During the centrifugal refining, the solid particles denser than the glass are thrown against the walls and trapped  
30 in the grooves 28 from which they can no longer emerge. On the other hand, the bubbles burst under the centripetal action towards the inside of the body of the centrifuger against the partition 34. Finally, in the lowest part of the part 30, the refined glass is  
35 drawn off via a channel by an approximately funnel-shaped receiving head 29. Under standard operating conditions, it is not necessary to provide glass-

heating means, the speed of rotation may be about 700 revolutions per minute and the height  $h$  of the centrifuger may be, for example, 1 to 3 metres.

A third embodiment is shown in Figure 4, which shows a melting chamber 2 identical to that in Figure 1, which in addition is schematic and contains a system for refining in multiple thin layers. Here, the melting and the refining are therefore carried out in the same melting chamber, the glass being drawn off at the bottom part via the discharge orifice 8' into a canal 8 in order to feed forming machines directly, especially machines for fiberizing mineral wool or for forming bottles and flasks (this refining system could also be placed in a downstream compartment). The principle of such refining is as follows: tubular elements 50 made of molybdenum (or platinum) are used, the rectangular cross section of which is shown in Figure 4d. These tubes are longitudinally partitioned by walls 51, thereby forming thin "lamellae" 52 open at the ends of the tube (for example 5 to 30 lamellae). These tubes 50 are submerged in the bath of vitrifiable materials being melted (hereafter termed "melt") as shown in Figure 4a (a longitudinal sectional view of the melting chamber) and Figure 4b (an elevation of the said chamber). The two tubes 50 are fastened to the side walls of the chamber, for example fixed to the walls by resting on ramps of refractory material, so as to be inclined at an angle  $\alpha$  with respect to the plane of the siege 4, or else along axes Y converging on the longitudinal axis X of the furnace at the said angle  $\alpha$ .

These two tubes 50 are arranged in this way as they may be easily fixed to the furnace walls and are at a significant distance from the burners. This configuration allows the molybdenum to be protected from the intense heating occurring near the burners. Likewise, it is preferable for these tubes to be

completely submerged in order to prevent them from oxidizing in the air, otherwise the alternative being to provide a non-oxidizing atmosphere above the melt (especially an  $N_2$  atmosphere). The two tubes 50 emerge  
5 in a collector tube 55 which feeds the discharge orifice 8 of the chamber.

The refining is carried out in the following manner: the gas to be refined enters the section of the tubes 50 in the top part 53 and then flows in the  
10 lamellae 52 in a descending path simply by gravity, as shown in Figure 4c illustrating a typical lamella 52. The velocity of the glass in these lamellae 52 is a maximum at the centre of the lamellae and much lower at the walls 53, 53' which contain them. As regards the  
15 bubbles 60, these very rapidly reach, by rising, the upper wall 53 of the lamella 52, thus separating from the descending flow of glass shown by the arrow in Figure 4c. Again, by rising, they are directed towards the inlet 66 of the tube 50, as a countercurrent to the  
20 glass flow, while the glass stripped of the bubbles reaches the bottom part 56 of the said lamella 52 and is removed directly via the collector 55 from the melting chamber.

The system is all the more effective the  
25 smaller the height  $h$  of each lamella 52 and the larger their surface area. This is particularly appropriate in the context of submerged-burner melting which tends to generate bubbles that have a relatively large diameter and therefore may be rapidly removed. It is possible to  
30 calculate the number, the height and the active surface area of these lamellae depending on the size of the bubbles to be removed, on the output of the melting chamber and on the viscosity of the glass, especially by also suitably choosing their length and angle of  
35 inclination according to the length of the melting chamber (or of the downstream compartment where they are located). By way of example, in the case of a

melting chamber manufacturing 200 tonnes of glass per day, in order to remove all bubbles having a diameter greater than 250 microns, the tubes 50 may have dimensions  $400 \times 520 \times 6550 \text{ mm}^3$  and may each contain 20  
5 lamellae, for a furnace length of about 6000 mm.

A variant of this embodiment consists in locating elements with similar lamellae in a downstream compartment.

In all cases (static or centrifugal refiner),  
10 it is clear that the size of the melting/refining apparatuses currently available may be spectacularly reduced. It has also been advantageous to add to the vitrifiable materials refining promoters, especially coke having a small particle size, sulphate, nitrate,  
15 fluorine or chlorine, the function of these promoters having been described above.

(In both the melting compartment and the refining compartment, it is possible to replace the molybdenum with platinum).

20 It is important to emphasize that, although the combination of melting by submerged burners with a refining step using reduced pressurization is extremely advantageous, the invention also relates to these two aspects taken separately. Thus, it may be advantageous  
25 to use the method of melting by submerged burners with a standard refining step and, reciprocally, to use a refining step with reduced pressurization following a melting step using conventional heating means, while still remaining within the scope of the invention, even  
30 if the synergy emphasized above is then no longer obtained.

It should also be noted that it may be advantageous to use the method of melting by submerged burners without any longer having to make any use of  
35 refining in the usual sense of the term. This may be the case in the field of fiberizing, in which it may be envisaged to feed the internal centrifugal fiberizing

CLAIMS

1. Process for melting and refining vitrifiable materials, **characterized in that** all or part of the thermal energy necessary for melting the said  
5 vitrifiable materials is supplied by the combustion of fuel(s) with at least one oxidizer gas, the said fuel(s)/gas or the gaseous products resulting from the combustion being injected below the level of the mass of vitrifiable materials (7) **and in that** the refining  
10 of the vitrifiable materials after melting takes place at least partly in the form of a "thin layer".
2. Process according to Claim 1, **characterized in that** the oxidizer is based on air, oxygen-enriched air or oxygen.
- 15 3. Process according to one of the preceding claims, **characterized in that** the melting of the vitrifiable materials takes place in at least one melting chamber (2) which is equipped with burners (5) passing through its side walls and/or passing through  
20 the sieve (4) and/or suspended from the roof (3) or from superstructures so that their combustion regions (6) or combustion gases develop in the mass of vitrifiable materials (7) being melted.
4. Process according to one of the preceding  
25 claims, **characterized in that** the combustion regions (6) created by the combustion of fossil fuel with the oxidizer gas(es) and/or the gases resulting from the said combustion convectively stir the vitrifiable materials (7).
- 30 5. Process according to Claim 3 or Claim 4, **characterized in that** the height of the mass of vitrifiable materials (7) in the melting chamber (2) and the height at which the combustion regions (6)/gases resulting from the combustion develop are  
35 adjusted so that the said fuels/combustion gases remain within the mass of the said vitrifiable materials.

09381631 030100

6. Process according to one of the preceding claims, **characterized in that** the melting is preceded by a step of preheating the vitrifiable materials to at most 900°C.
- 5 7. Process according to one of the preceding claims, **characterized in that** the vitrifiable materials comprise batch materials and/or cullet and/or vitrifiable scrap and/or combustible elements, especially glass-plastic composites, glass-metal
- 10 composites, organic materials, or coal.
8. Process according to one of the preceding claims, **characterized in that** the refining operation is carried out on the molten vitrifiable materials of the glass type in the foamy state, having especially a
- 15 density of approximately 0.5 to 2 g/cm<sup>3</sup>.
9. Process according to Claim 8, **characterized in that** the refining is carried out on molten vitrifiable materials of the glass type in the foamy state, most of the bubbles being at least 100 or even at least 200 μm
- 20 in diameter.
10. Process according to one of the preceding claims, **characterized in that** the vitrifiable materials contain refining promoters, especially reducing additives of the coke type, preferably having an
- 25 average particle size of less than 200 μm, sulphates, or fluorine- or chlorine-based additives, or nitrates of the NaNO<sub>3</sub> type.
11. Process according to one of the preceding claims, **characterized in that** the melting is carried
- 30 out at 1400°C at most, especially 1380 or 1350°C at most, and the refining at 1500°C at most.
12. Process according to one of the preceding claims, **characterized in that** the refining is carried out in at least one static compartment lying downstream
- 35 of the melting chamber (2), of the flow-canal type (9), and provided with one or more means for forcing the

09381634 030400

chamber (2) below the level of the mass of vitrifiable materials being melted.

18. Apparatus for melting and refining vitrifiable materials, especially intended for implementing the process according to one of the preceding claims,  
5 **characterized in that** it comprises:

→ at least one melting chamber (2) equipped with burners (5) which are fed with fossil fuel(s) of the natural gas type and with oxidizer(s) of the air or oxygen type, the said burners being placed so as to  
10 inject the said fuels/gases or gases resulting from their combustion below the level of the mass (7) of vitrifiable materials introduced into the said melting chamber;

15 → means for refining the molten vitrifiable materials in the form of a "thin layer", in the actual melting chamber (2) or in at least one refining compartment (9, 21) downstream of the said chamber.

19. Apparatus according to Claim 18, **characterized in that** the refining compartment(s) (9) is(are) static and has(have) a flow canal comprising a channel (10) and a roof (11), the one or more means of forcing the molten vitrifiable materials to be refined in the said canal in a thin layer, with flow of the plug-flow type,  
20 especially over a depth of less than 15 cm, being at least the selection of the ratio of the average height to the average width of the said canal, this ratio being less than 1 and especially less than 0.5.

20. Apparatus according to Claim 18 or 19, **characterized in that** the refining compartment(s)  
30 is(are) static and has(have) a flow canal comprising a channel (10) and a roof (11), the one or more means for forcing the molten vitrifiable materials to be refined in the said canal in a thin layer, especially over a  
35 depth of less than 15 cm, being at least one or more means for adjusting/regulating the flow of the molten

00381631 000100

vitrifiable materials at the inlet and/or at the outlet of the refining compartment (9).

21. Apparatus according to one of Claims 18 to 20, **characterized in that** the flow canal (9) is equipped with heating means, especially of the type having oxygen burners (13), above the molten vitrifiable materials.

22. Apparatus according to one of Claims 18 to 21, **characterized in that** the flow canal is provided with means for homogenizing the vitrifiable materials.

23. Apparatus according to Claim 18, **characterized in that** the melting chamber (2), or a refining compartment downstream of the latter, comprises at least one structural means for thin-film refining, in the form of at least two adjacent walls (53, 53') which are approximately mutually parallel, intended to be at least partially submerged in the mass of molten vitrifiable materials and inclined with respect to the sieve of the said chamber or of the said compartment.

24. Apparatus according to Claim 23, **characterized in that** these walls are incorporated into at least one longitudinally partitioned tubular element (50), especially having an approximately rectangular section.

25. Apparatus according to Claim 24, **characterized in that** this or these tubular element(s) (50) (is) are in the melting chamber (2) and emerge(s) in the discharge opening (8) downstream of the said chamber.

26. Apparatus according to Claim 18, **characterized in that** the refining compartment includes at least one device (21) capable of being rotated in order to ensure centrifugal refining, the internal walls (33) of the said device defining approximately a cavity in the form of a hollow cylinder which is vertical in its central part.

27. Apparatus according to Claim 26, **characterized in that** the device (21) capable of being rotated is

09381631 030100

provided in the cavity with partitions (34) over at least part of its height, forcing the molten vitrifiable materials to flow between the internal walls (33) of the device and the said partitions (34),  
5 the average distance between the walls and the partitions defining the "thickness" of the thin layer.

28. Apparatus according to Claim 27, **characterized in that** the average distance between the walls and the partitions is defined by a ratio of their radii  $R1/R0$   
10 of at least 0.8.

29. Apparatus according to one of Claims 26 to 28, **characterized in that** the walls of the device are lined with refractory pieces (32) of the electrocast type, these including a thermal insulator (31) incorporated  
15 so as to avoid being crushed by the centrifugal force.

30. Apparatus according to one of Claims 26 to 29, **characterized in that** the device (21) is provided with one or more means for trapping solid particles, these being especially located in its lower zone (23) and  
20 being in the form of notches/grooves (28) made in its internal walls (33).

31. Apparatus according to one of Claims 18 to 30, characterized in that the melting chamber (2) is equipped with at least one means of introducing  
25 vitrifiable materials below the level of the mass of vitrifiable materials being melted, especially at least two of them, preferably in the form of one or more openings associated with a supply means of the feed-screw type.

30 32. Apparatus according to one of Claims 18 to 31, **characterized in that** the walls of the melting chamber (2), especially those intended to be in contact with the mass of vitrifiable materials being melted, are based on refractory materials associated with a cooling  
35 system using a fluid of the water type.

33. Apparatus according to one of Claims 18 to 32,

00331631 030100

**characterized in that** the walls of the melting chamber (2), especially those intended to be in contact with the mass of vitrifiable materials being melted, are based on refractory materials lined with a lining of metal (40) of the molybdenum type.

34. Apparatus according to Claim 33, **characterized in that** the said lining (40) is held at some distance from the walls consisting of the refractory materials.

35. Apparatus according to Claim 33 or 34, **characterized in that** the said lining constitutes a surface for contact with the molten materials which is continuous or drilled with holes (41).

36. Apparatus according to one of Claims 18 to 35, **characterized in that** at least some of the burners (5) of the melting chamber (2) are designed to also be able to inject, into the mass of vitrifiable materials, a fluid which does not participate in the combustion, as a substitute for the oxidizer and/or the fuel, especially an inert gas of the N<sub>2</sub> type and/or a coolant of the water type.

37. Application of the process according to one of Claims 1 to 18 or of the apparatus according to one of Claims 19 to 36 to the manufacture of flat glass, especially flat glass having a residual blue colour and a solar-protection or fire-resistance function, for the electronics industry, to the manufacture of glass hollow-ware of the bottle or flask type, or to the manufacture of glass wool or of glass fibre for reinforcement.

PATENT

PROCESS FOR MELTING AND REFINING  
VITRIFIABLE MATERIALS

Filed by: SAINT-GOBAIN VITRAGE

ABSTRACT

The subject of the invention is a process for melting and refining vitrifiable materials, such that all or part of the thermal energy necessary for melting the said vitrifiable materials is supplied by the combustion of fossil fuel(s) with at least one oxidizer gas, the said fuel(s)/gas or the gaseous products resulting from the combustion being injected below the level of the mass of vitrifiable materials (7). The refining of the vitrifiable materials after melting takes place at least partly in the form of a "thin layer".

The invention also relates to the device for implementing the process and to its applications.
